
PVLIB_Python Documentation

Release 0.2.0

Sandia National Labs, Rob Andrews, University of Arizona, [github](#)

November 17, 2014

1	Modules	3
1.1	atmosphere module	3
1.2	clearsky module	5
1.3	irradiance module	8
1.4	location module	18
1.5	pvsystem module	18
1.6	solarposition module	29
1.7	tmy module	31
1.8	tools module	36
2	Indices and tables	39
	Python Module Index	41

This is the documentation for the University of Arizona PVLIB fork hosted at https://github.com/UARENForecasting/PVLIB_Python

The official Sandia repo is hosted at https://github.com/Sandia-Labs/PVLIB_Python

You may also want to browser the tutorials using nbviewer at http://nbviewer.ipython.org/github/UARENForecasting/PVLIB_Python/tree

Contents:

1.1 atmosphere module

The atmosphere module contains methods to calculate relative and absolute airmass and to determine pressure from altitude or vice versa.

`pvlib.atmosphere.absoluteairmass` (*AMrelative*, *pressure=101325.0*)

Determine absolute (pressure corrected) airmass from relative airmass and pressure

Gives the airmass for locations not at sea-level (i.e. not at standard pressure). The input argument “AMrelative” is the relative airmass. The input argument “pressure” is the pressure (in Pascals) at the location of interest and must be greater than 0. The calculation for absolute airmass is

$$absoluteairmass = (relativeairmass) * pressure / 101325$$

Parameters *AMrelative* : scalar or Series

The airmass at sea-level.

pressure : scalar or Series

The site pressure in Pascal.

Returns scalar or Series

Absolute (pressure corrected) airmass

See also:

`relativeairmass`

References

[1] C. Gueymard, “Critical analysis and performance assessment of clear sky solar irradiance models using theoretical and measured data,” *Solar Energy*, vol. 51, pp. 121-138, 1993.

`pvlib.atmosphere.alt2pres` (*altitude*)

Determine site pressure from altitude

Parameters *Altitude* : scalar or Series

Altitude in meters above sea level

Returns *Pressure* : scalar or Series

Atmospheric pressure (Pascals)

Notes

The following assumptions are made

Parameter	Value
Base pressure	101325 Pa
Temperature at zero altitude	288.15 K
Gravitational acceleration	9.80665 m/s ²
Lapse rate	-6.5E-3 K/m
Gas constant for air	287.053 J/(kgK)
Relative Humidity	0%

References

“A Quick Derivation relating altitude to air pressure” from Portland State Aerospace Society, Version 1.03, 12/22/2004.

`pvlb.atmosphere.pres2alt` (*pressure*)

Determine altitude from site pressure

Parameters **Pressure** : scalar or Series

Atmospheric pressure (Pascals)

Returns **altitude** : scalar or Series

Altitude in meters above sea level

Notes

The following assumptions are made

Parameter	Value
Base pressure	101325 Pa
Temperature at zero altitude	288.15 K
Gravitational acceleration	9.80665 m/s ²
Lapse rate	-6.5E-3 K/m
Gas constant for air	287.053 J/(kgK)
Relative Humidity	0%

References

“A Quick Derivation relating altitude to air pressure” from Portland State Aerospace Society, Version 1.03, 12/22/2004.

`pvlb.atmosphere.relativeairmass` (*z*, *model*=*'kastenyoung1989'*)

Gives the relative (not pressure-corrected) airmass

Gives the airmass at sea-level when given a sun zenith angle, *z* (in degrees). The “model” variable allows selection of different airmass models (described below). “model” must be a valid string. If “model” is not included or is not valid, the default model is *'kastenyoung1989'*.

Parameters **z** : float or DataFrame

Zenith angle of the sun in degrees. Note that some models use the apparent (refraction corrected) zenith angle, and some models use the true (not refraction-corrected) zenith angle. See model descriptions to determine which type of zenith angle is required. Apparent zenith angles must be calculated at sea level.

model : String

Available models include the following:

- ‘simple’ - secant(apparent zenith angle) - Note that this gives -inf at zenith=90
- ‘kasten1966’ - See reference [1] - requires apparent sun zenith
- ‘youngirvine1967’ - See reference [2] - requires true sun zenith
- ‘kastenyoung1989’ - See reference [3] - requires apparent sun zenith
- ‘gueymard1993’ - See reference [4] - requires apparent sun zenith
- ‘young1994’ - See reference [5] - requires true sun zenith
- ‘pickering2002’ - See reference [6] - requires apparent sun zenith

Returns **AM** : float or DataFrame

Relative airmass at sea level. Will return NaN values for any zenith angle greater than 90 degrees.

1.2 clearsky module

Contains several methods to calculate clear sky GHI, DNI, and DHI.

`pvlib.clearsky.disc(GHI, SunZen, Time, pressure=101325)`

Estimate Direct Normal Irradiance from Global Horizontal Irradiance using the DISC model

The DISC algorithm converts global horizontal irradiance to direct normal irradiance through empirical relationships between the global and direct clearness indices.

Parameters **GHI** : float or DataFrame

global horizontal irradiance in W/m². GHI must be ≥ 0 .

Z : float or DataFrame

True (not refraction - corrected) zenith angles in decimal degrees. Z must be ≥ 0 and ≤ 180 .

doy : float or DataFrame

the day of the year. doy must be ≥ 1 and < 367 .

Returns DNI : float or DataFrame

The modeled direct normal irradiance in W/m^2 provided by the Direct Insolation Simulation Code (DISC) model.

Kt : float or DataFrame

Ratio of global to extraterrestrial irradiance on a horizontal plane.

Other Parameters pressure : float or DataFrame (optional, Default=101325)

site pressure in Pascal. Pressure may be measured or an average pressure may be calculated from site altitude. If pressure is omitted, standard pressure (101325 Pa) will be used, this is acceptable if the site is near sea level. If the site is not near sea level, inclusion of a measured or average pressure is highly recommended.

`pvlb.clearsky.haurwitz` (*ApparentZenith*)

Determine clear sky GHI from Haurwitz model

Implements the Haurwitz clear sky model for global horizontal irradiance (GHI) as presented in [1, 2]. A report on clear sky models found the Haurwitz model to have the best performance of models which require only zenith angle [3]. Extreme care should be taken in the interpretation of this result!

Parameters ApparentZenith : DataFrame

The apparent (refraction corrected) sun zenith angle in degrees.

Returns `pd.Series`. The modeled global horizontal irradiance in W/m^2 provided

by the Haurwitz clear-sky model.

Initial implementation of this algorithm by Matthew Reno.

```
pvlib.clearsky.ineichen(time, location, linke_turbidity=None, solarposition_method='pyephem',
                        zenith_data=None, airmass_model='young1994', airmass_data=None,
                        interp_turbidity=True)
```

Determine clear sky GHI, DNI, and DHI from Ineichen/Perez model

Implements the Ineichen and Perez clear sky model for global horizontal irradiance (GHI), direct normal irradiance (DNI), and calculates the clear-sky diffuse horizontal (DHI) component as the difference between GHI and $DNI \cdot \cos(\text{zenith})$ as presented in [1, 2]. A report on clear sky models found the Ineichen/Perez model to have excellent performance with a minimal input data set [3]. Default values for Linke turbidity provided by SoDa [4, 5].

Parameters `time` : pandas.DatetimeIndex

`location` : pvlib.Location

`linke_turbidity` : None or float

`solarposition_method` : string

See pvlib.solarposition.get_solarposition()

`zenith_data` : None or pandas.Series

If None, ephemeris data will be calculated using `solarposition_method`.

`airmass_model` : string

See pvlib.airmass.relativeairmass().

`airmass_data` : None or pandas.Series

If None, absolute air mass data will be calculated using `airmass_model` and `location.altitude`.

Returns `ClearSkyGHI` : Dataframe.

the modeled global horizontal irradiance in W/m^2 provided by the Ineichen clear-sky model.

`ClearSkyDNI` : Dataframe.

the modeled direct normal irradiance in W/m^2 provided by the Ineichen clear-sky model.

`ClearSkyDHI` : Dataframe.

the calculated diffuse horizontal irradiance in W/m^2 provided by the Ineichen clear-sky model.

Notes

If you are using this function in a loop, it may be faster to load `LinkeTurbidities.mat` outside of the loop and feed it in as a variable, rather than having the function open the file each time it is called.

1.3 irradiance module

`pvlb.irradiance.aoi` (*surf_tilt, surf_az, sun_zen, sun_az*)

Calculates the angle of incidence of the solar vector on a surface. This is the angle between the solar vector and the surface normal.

Input all angles in degrees.

Parameters `surf_tilt` : float or Series.

Panel tilt from horizontal.

`surf_az` : float or Series.

Panel azimuth from north.

`sun_zen` : float or Series.

Solar zenith angle.

`sun_az` : float or Series.

Solar azimuth angle.

Returns float or Series. Angle of incidence in degrees.

`pvlb.irradiance.aoi_projection` (*surf_tilt, surf_az, sun_zen, sun_az*)

Calculates the dot product of the solar vector and the surface normal.

Input all angles in degrees.

Parameters `surf_tilt` : float or Series.

Panel tilt from horizontal.

`surf_az` : float or Series.

Panel azimuth from north.

`sun_zen` : float or Series.

Solar zenith angle.

`sun_az` : float or Series.

Solar azimuth angle.

Returns float or Series. Dot product of panel normal and solar angle.

`pvlb.irradiance.beam_component` (*surf_tilt, surf_az, sun_zen, sun_az, DNI*)

Calculates the beam component of the plane of array irradiance.

`pvlb.irradiance.extraradiation` (*datetime_or_doy, solar_constant=1366.1, method='spencer'*)

Determine extraterrestrial radiation from day of year.

Parameters `datetime_or_doy` : int, float, array, `pd.DatetimeIndex`

Day of year, array of days of year e.g. `pd.DatetimeIndex.dayofyear`, or `pd.DatetimeIndex`.

solar_constant : float

The solar constant.

method : string

The method by which the ET radiation should be calculated. Options include 'pyephem', 'spencer', 'asce'.

Returns float or Series

The extraterrestrial radiation present in watts per square meter on a surface which is normal to the sun. Ea is of the same size as the input doyear.

'pyephem' always returns a series.

See also:

`disc`

Notes

The Spencer method contains a minus sign discrepancy between equation 12 of [1]. It's unclear what the correct formula is.

`pvlb.irradiance.globalinplane` (*SurfTilt, SurfAz, AOI, DNI, In_Plane_SkyDiffuse, GR*)

Determine the three components on in-plane irradiance

Combines in-plane irradiance components from the chosen diffuse transmittance, ground reflection and beam irradiance algorithms into the total in-plane irradiance.

Parameters `SurfTilt` : float or DataFrame

surface tilt angles in decimal degrees. `SurfTilt` must be ≥ 0 and ≤ 180 . The tilt angle is defined as degrees from horizontal (e.g. surface facing up = 0, surface facing horizon = 90)

SurfAz : float or DataFrame

Surface azimuth angles in decimal degrees. SurfAz must be ≥ 0 and ≤ 360 . The Azimuth convention is defined as degrees east of north (e.g. North = 0, south=180, East = 90, West = 270).

AOI : float or DataFrame

Angle of incidence of solar rays with respect to the module surface, from `pvl_getaoi`. AOI must be ≥ 0 and ≤ 180 .

DNI : float or DataFrame

Direct normal irradiance (W/m^2), as measured from a TMY file or calculated with a clearsky model.

In_Plane_SkyDiffuse : float or DataFrame

Diffuse irradiance (W/m^2) in the plane of the modules, as calculated by a diffuse irradiance translation function

GR : float or DataFrame

a scalar or DataFrame of ground reflected irradiance (W/m^2), as calculated by a albedo model (eg. `pvl_grounddiffuse`)

Returns E : float or DataFrame

Total in-plane irradiance (W/m^2)

Eb : float or DataFrame

Total in-plane beam irradiance (W/m^2)

Ediff : float or DataFrame

Total in-plane diffuse irradiance (W/m^2)

See also:

`pvl.lib.irradiance.grounddiffuse` (*surf_tilt*, *ghi*, *albedo=0.25*, *surface_type=None*)

Estimate diffuse irradiance from ground reflections given irradiance, albedo, and surface tilt

Function to determine the portion of irradiance on a tilted surface due to ground reflections. Any of the inputs may be DataFrames or scalars.

Parameters surf_tilt : float or DataFrame

Surface tilt angles in decimal degrees. SurfTilt must be ≥ 0 and ≤ 180 . The tilt angle is defined as degrees from horizontal (e.g. surface facing up = 0, surface facing horizon = 90).

ghi : float or DataFrame

Global horizontal irradiance in W/m^2 .

albedo : float or DataFrame

Ground reflectance, typically 0.1-0.4 for surfaces on Earth (land), may increase over snow, ice, etc. May also be known as the reflection coefficient. Must be ≥ 0 and ≤ 1 . Will be overridden if *surface_type* is supplied.

surface_type: None or string in

‘urban’, ‘grass’, ‘fresh grass’, ‘snow’, ‘fresh snow’, ‘asphalt’, ‘concrete’, ‘aluminum’, ‘copper’, ‘fresh steel’, ‘dirty steel’. Overrides albedo.

Returns float or DataFrame

Ground reflected irradiances in W/m².

`pvl.lib.irradiance.haydavies` (*surf_tilt*, *surf_az*, *DHI*, *DNI*, *DNI_ET*, *sun_zen*, *sun_az*)

Determine diffuse irradiance from the sky on a tilted surface using Hay & Davies’ 1980 model

$$I_d = DHI(AR_b + (1 - A)(\frac{1 + \cos \beta}{2}))$$

Hay and Davies’ 1980 model determines the diffuse irradiance from the sky (ground reflected irradiance is not included in this algorithm) on a tilted surface using the surface tilt angle, surface azimuth angle, diffuse horizontal irradiance, direct normal irradiance, extraterrestrial irradiance, sun zenith angle, and sun azimuth angle.

Parameters *surf_tilt* : float or Series

Surface tilt angles in decimal degrees. The tilt angle is defined as degrees from horizontal (e.g. surface facing up = 0, surface facing horizon = 90)

surf_az : float or Series

Surface azimuth angles in decimal degrees. The Azimuth convention is defined as degrees east of north (e.g. North = 0, South=180 East = 90, West = 270).

DHI : float or Series

diffuse horizontal irradiance in W/m².

DNI : float or Series

direct normal irradiance in W/m².

DNI_ET : float or Series

extraterrestrial normal irradiance in W/m².

sun_zen : float or Series

apparent (refraction-corrected) zenith angles in decimal degrees.

sun_az : float or Series

Sun azimuth angles in decimal degrees. The Azimuth convention is defined as degrees east of north (e.g. North = 0, East = 90, West = 270).

Returns *SkyDiffuse* : float or Series

the diffuse component of the solar radiation on an arbitrarily tilted surface defined by the Perez model as given in reference [3]. *SkyDiffuse* is the diffuse component ONLY and does not include the ground reflected irradiance or the irradiance due to the beam.

`pvl.lib.irradiance.isotropic` (*surf_tilt*, *DHI*)

Determine diffuse irradiance from the sky on a tilted surface using the isotropic sky model.

$$I_d = DHI \frac{1 + \cos \beta}{2}$$

Hottel and Woertz’s model treats the sky as a uniform source of diffuse irradiance. Thus the diffuse irradiance from the sky (ground reflected irradiance is not included in this algorithm) on a tilted surface can be found from the diffuse horizontal irradiance and the tilt angle of the surface.

Parameters `surf_tilt` : float or Series

Surface tilt angle in decimal degrees. `surf_tilt` must be ≥ 0 and ≤ 180 . The tilt angle is defined as degrees from horizontal (e.g. surface facing up = 0, surface facing horizon = 90)

DHI : float or Series

Diffuse horizontal irradiance in W/m^2 . DHI must be ≥ 0 .

Returns float or Series

The diffuse component of the solar radiation on an arbitrarily tilted surface defined by the isotropic sky model as given in Loutzenhiser et. al (2007) equation 3.

SkyDiffuse is the diffuse component ONLY and does not include the ground reflected irradiance or the irradiance due to the beam.

SkyDiffuse is a column vector with a number of elements equal to the input vector(s).

`pvl.lib.irradiance.king` (*surf_tilt*, *DHI*, *GHI*, *sun_zen*)

Determine diffuse irradiance from the sky on a tilted surface using the King model

King's model determines the diffuse irradiance from the sky (ground reflected irradiance is not included in this algorithm) on a tilted surface using the surface tilt angle, diffuse horizontal irradiance, global horizontal irradiance, and sun zenith angle. Note that this model is not well documented and has not been published in any fashion (as of January 2012).

Parameters *surf_tilt* : float or Series

Surface tilt angles in decimal degrees. The tilt angle is defined as degrees from horizontal (e.g. surface facing up = 0, surface facing horizon = 90)

DHI : float or Series

diffuse horizontal irradiance in W/m².

GHI : float or Series

global horizontal irradiance in W/m².

sun_zen : float or Series

apparent (refraction-corrected) zenith angles in decimal degrees.

Returns *SkyDiffuse* : float or Series

the diffuse component of the solar radiation on an arbitrarily tilted surface as given by a model developed by David L. King at Sandia National Laboratories.

See also:

`pvl.ephemeris`, `pvl.extraradiation`, `pvl.isotropicsky`, `pvl.haydavies1980`, `pvl.perez`, `pvl.klucher1979`, `pvl.reindl1990`

`pvl.lib.irradiance.klucher` (*surf_tilt*, *surf_az*, *DHI*, *GHI*, *sun_zen*, *sun_az*)

Determine diffuse irradiance from the sky on a tilted surface using Klucher's 1979 model

$$I_d = DHI \frac{1 + \cos \beta}{2} (1 + F' \sin^3(\beta/2)) (1 + F' \cos^2 \theta \sin^3 \theta_z)$$

where

$$F' = 1 - (I_{d0}/GHI)$$

Klucher's 1979 model determines the diffuse irradiance from the sky (ground reflected irradiance is not included in this algorithm) on a tilted surface using the surface tilt angle, surface azimuth angle, diffuse horizontal irradiance, direct normal irradiance, global horizontal irradiance, extraterrestrial irradiance, sun zenith angle, and sun azimuth angle.

Parameters *surf_tilt* : float or Series

Surface tilt angles in decimal degrees. *surf_tilt* must be ≥ 0 and ≤ 180 . The tilt angle is defined as degrees from horizontal (e.g. surface facing up = 0, surface facing horizon = 90)

surf_az : float or Series

Surface azimuth angles in decimal degrees. *surf_az* must be ≥ 0 and ≤ 360 . The Azimuth convention is defined as degrees east of north (e.g. North = 0, South=180 East = 90, West = 270).

DHI : float or Series

diffuse horizontal irradiance in W/m². DHI must be ≥ 0 .

GHI : float or Series

Global irradiance in W/m^2 . DNI must be ≥ 0 .

sun_zen : float or Series

apparent (refraction-corrected) zenith angles in decimal degrees. sun_zen must be ≥ 0 and ≤ 180 .

sun_az : float or Series

Sun azimuth angles in decimal degrees. sun_az must be ≥ 0 and ≤ 360 . The Azimuth convention is defined as degrees east of north (e.g. North = 0, East = 90, West = 270).

Returns float or Series.

The diffuse component of the solar radiation on an arbitrarily tilted surface defined by the Klucher model as given in Loutzenhiser et. al (2007) equation 4.

SkyDiffuse is the diffuse component ONLY and does not include the ground reflected irradiance or the irradiance due to the beam.

SkyDiffuse is a column vector with a number of elements equal to the input vector(s).

`pvl.lib.irradiance.perez(surf_tilt, surf_az, DHI, DNI, DNI_ET, sun_zen, sun_az, AM, modelt='allsitescomposite1990')`

Determine diffuse irradiance from the sky on a tilted surface using one of the Perez models

Perez models determine the diffuse irradiance from the sky (ground reflected irradiance is not included in this algorithm) on a tilted surface using the surface tilt angle, surface azimuth angle, diffuse horizontal irradiance, direct normal irradiance, extraterrestrial irradiance, sun zenith angle, sun azimuth angle, and relative (not pressure-corrected) airmass. Optionally a selector may be used to use any of Perez's model coefficient sets.

Parameters surf_tilt : float or Series

Surface tilt angles in decimal degrees. surf_tilt must be ≥ 0 and ≤ 180 . The tilt angle is defined as degrees from horizontal (e.g. surface facing up = 0, surface facing horizon = 90)

surf_az : float or Series

Surface azimuth angles in decimal degrees. surf_az must be ≥ 0 and ≤ 360 . The Azimuth convention is defined as degrees east of north (e.g. North = 0, South=180 East = 90, West = 270).

DHI : float or Series

diffuse horizontal irradiance in W/m^2 . DHI must be ≥ 0 .

DNI : float or Series

direct normal irradiance in W/m^2 . DNI must be ≥ 0 .

DNI_ET : float or Series

extraterrestrial normal irradiance in W/m^2 . DNI_ET must be ≥ 0 .

sun_zen : float or Series

apparent (refraction-corrected) zenith angles in decimal degrees. sun_zen must be ≥ 0 and ≤ 180 .

sun_az : float or Series

Sun azimuth angles in decimal degrees. sun_az must be ≥ 0 and ≤ 360 . The Azimuth convention is defined as degrees east of north (e.g. North = 0, East = 90, West = 270).

AM : float or Series

relative (not pressure-corrected) airmass values. If AM is a DataFrame it must be of the same size as all other DataFrame inputs. AM must be ≥ 0 (careful using the 1/sec(z) model of AM generation)

Returns float or Series

the diffuse component of the solar radiation on an arbitrarily tilted surface defined by the Perez model as given in reference [3]. SkyDiffuse is the diffuse component ONLY and does not include the ground reflected irradiance or the irradiance due to the beam.

Other Parameters model : string (optional, default='allsitescomposite1990')

a character string which selects the desired set of Perez coefficients. If model is not provided as an input, the default, '1990' will be used. All possible model selections are:

- '1990'
- 'allsitescomposite1990' (same as '1990')
- 'allsitescomposite1988'
- 'sandiacomposite1988'

`pvlb. irradiance.poa_horizontal_ratio` (*surf_tilt*, *surf_az*, *sun_zen*, *sun_az*)

Calculates the ratio of the beam components of the plane of array irradiance and the horizontal irradiance.

Input all angles in degrees.

Parameters *surf_tilt* : float or Series.

Panel tilt from horizontal.

surf_az : float or Series.

Panel azimuth from north.

sun_zen : float or Series.

Solar zenith angle.

sun_az : float or Series.

Solar azimuth angle.

Returns float or Series. Ratio of the plane of array irradiance to the horizontal plane irradiance

`pvlb. irradiance.reindl` (*surf_tilt*, *surf_az*, *DHI*, *DNI*, *GHI*, *DNI_ET*, *sun_zen*, *sun_az*)

Determine diffuse irradiance from the sky on a tilted surface using Reindl's 1990 model

$$I_d = DHI(AR_b + (1 - A)(\frac{1 + \cos \beta}{2})(1 + \sqrt{\frac{I_{hb}}{I_h}} \sin^3(\beta/2)))$$

Reindl's 1990 model determines the diffuse irradiance from the sky (ground reflected irradiance is not included in this algorithm) on a tilted surface using the surface tilt angle, surface azimuth angle, diffuse horizontal irradiance, direct normal irradiance, global horizontal irradiance, extraterrestrial irradiance, sun zenith angle, and sun azimuth angle.

Parameters *surf_tilt* : float or Series.

Surface tilt angles in decimal degrees. The tilt angle is defined as degrees from horizontal (e.g. surface facing up = 0, surface facing horizon = 90)

surf_az : float or Series.

Surface azimuth angles in decimal degrees. The Azimuth convention is defined as degrees east of north (e.g. North = 0, South=180 East = 90, West = 270).

DHI : float or Series.

diffuse horizontal irradiance in W/m².

DNI : float or Series.

direct normal irradiance in W/m².

GHI: float or Series.

Global irradiance in W/m².

DNI_ET : float or Series.

extraterrestrial normal irradiance in W/m².

sun_zen : float or Series.

apparent (refraction-corrected) zenith angles in decimal degrees.

sun_az : float or Series.

Sun azimuth angles in decimal degrees. The Azimuth convention is defined as degrees east of north (e.g. North = 0, East = 90, West = 270).

Returns SkyDiffuse : float or Series.

The diffuse component of the solar radiation on an arbitrarily tilted surface defined by the Reindl model as given in Loutzenhiser et. al (2007) equation 8. SkyDiffuse is the diffuse component ONLY and does not include the ground reflected irradiance or the irradiance due to the beam. SkyDiffuse is a column vector with a number of elements equal to the input vector(s).

`pvl_perez`, `pvl_klucher1979`, `pvl_kingdiffuse`

Notes

The POAskydiffuse calculation is generated from the Loutzenhiser et al. (2007) paper, equation 8. Note that I have removed the beam and ground reflectance portion of the equation and this generates ONLY the diffuse radiation from the sky and circumsolar, so the form of the equation varies slightly from equation 8.

1.4 location module

This module contains the Location class.

class `pvlb.location.Location` (*latitude, longitude, tz='US/Mountain', altitude=100, name=None*)
Bases: `object`

Location objects are convenient containers for latitude, longitude, timezone, and altitude data associated with a particular geographic location. You can also assign a name to a location object.

Location objects have two timezone attributes:

- `location.tz` is a IANA timezone string.
- `location.pytz` is a pytz timezone object.

Location objects support the print method.

1.5 pvsystem module

`pvlb.pvsystem.I_from_V` (*Rsh, Rs, nNsVth, V, IO, IL*)
calculates I from V per Eq 2 Jain and Kapoor 2004 uses Lambert W implemented in `wapr_vec.m` Rsh, nVth, V, IO, IL can all be DataFrames Rs can be a DataFrame, but should be a scalar

`pvlb.pvsystem.Voc_optfcn` (*df, loc*)
Function to find V_{oc} from I_{from_V}

`pvlb.pvsystem.ashraeiam` (*b, theta*)
Determine the incidence angle modifier using the ASHRAE transmission model.

`ashraeiam` calculates the incidence angle modifier as developed in [1], and adopted by ASHRAE (American Society of Heating, Refrigeration, and Air Conditioning Engineers) [2]. The model has been used by model programs such as PVSyst [3].

Note: For incident angles near 90 degrees, this model has a discontinuity which has been addressed in this function.

Parameters *b* : float

A parameter to adjust the modifier as a function of angle of incidence. Typical values are on the order of 0.05 [3].

theta : Series

The angle of incidence between the module normal vector and the sun-beam vector in degrees.

Returns *IAM* : Series

The incident angle modifier calculated as $1-b*(\sec(\theta)-1)$ as described in [2,3].

Returns nan for all $\text{abs}(\theta) \geq 90$ and for all IAM values that would be less than 0.

[3] PVsyst Contextual Help. http://files.pvsyst.com/help/index.html?iam_loss.htm retrieved on September 10, 2012

`pvl.lib.pvsystem.calcparams_desoto` (*S*, *Tcell*, *alpha_isc*, *module_parameters*, *EgRef*, *dEgdT*, *M=1*,
Sref=1000, *Tref=25*)

Applies the temperature and irradiance corrections to inputs for singlediode.

Applies the temperature and irradiance corrections to the IL, I0, Rs, Rsh, and a parameters at reference conditions (IL_ref, I0_ref, etc.) according to the De Soto et. al description given in [1]. The results of this correction procedure may be used in a single diode model to determine IV curves at irradiance = S, cell temperature = Tcell.

Parameters *S* : float or DataFrame

The irradiance (in W/m²) absorbed by the module. S must be >= 0. Due to a division by S in the script, any S value equal to 0 will be set to 1E-10.

Tcell : float or DataFrame

The average cell temperature of cells within a module in C. Tcell must be >= -273.15.

alpha_isc : float

The short-circuit current temperature coefficient of the module in units of 1/C.

module_parameters : dict or Series

Parameters describing PV module performance at reference conditions according to DeSoto’s paper. Parameters may be generated or found by lookup. For ease of use, `retrieve_sam` can automatically generate a dict based on the most recent SAM CEC module database. The `module_parameters` dict must contain the following 5 fields:

- *a_ref* - modified diode ideality factor parameter at reference conditions (units of eV), *a_ref* can be calculated from the usual diode ideality factor (*n*), number of cells in series (*Ns*), and cell temperature (*Tcell*) per equation (2) in [1].
- *IL_ref* - Light-generated current (or photocurrent) in amperes at reference conditions. This value is referred to as *Iph* in some literature.
- *I0_ref* - diode reverse saturation current in amperes, under reference conditions.
- *Rsh_ref* - shunt resistance under reference conditions (ohms).
- *Rs_ref* - series resistance under reference conditions (ohms).

EgRef : float

The energy bandgap at reference temperature (in eV). 1.121 eV for silicon. *EgRef* must be >0.

dEgdT : float

The temperature dependence of the energy bandgap at SRC (in 1/C). May be either a scalar value (e.g. -0.0002677 as in [1]) or a DataFrame of dEgdT values corresponding to each input condition (this may be useful if dEgdT is a function of temperature).

Returns **IL** : float or DataFrame

Light-generated current in amperes at irradiance=S and cell temperature=Tcell.

I0 : float or DataFrame

Diode saturation current in amperes at irradiance S and cell temperature Tcell.

Rs : float

Series resistance in ohms at irradiance S and cell temperature Tcell.

Rsh : float or DataFrame

Shunt resistance in ohms at irradiance S and cell temperature Tcell.

nNsVth : float or DataFrame

Modified diode ideality factor at irradiance S and cell temperature Tcell. Note that in source [1] $nNsV_{th} = a$ (equation 2). $nNsV_{th}$ is the product of the usual diode ideality factor (n), the number of series-connected cells in the module (Ns), and the thermal voltage of a cell in the module (Vth) at a cell temperature of Tcell.

Other Parameters **M** : float or DataFrame (optional, Default=1)

An optional airmass modifier, if omitted, M is given a value of 1, which assumes absolute (pressure corrected) airmass = 1.5. In this code, M is equal to M/M_{ref} as described in [1] (i.e. M_{ref} is assumed to be 1). Source [1] suggests that an appropriate value for M as a function absolute airmass (AMa) may be:

```
>>> M = np.polyval([-0.000126, 0.002816, -0.024459, 0.086257, 0.918093], AMa)
```

M may be a DataFrame.

Sref : float (optional, Default=1000)

Optional reference irradiance in W/m². If omitted, a value of 1000 is used.

Tref : float (Optional, Default=25)

Optional reference cell temperature in C. If omitted, a value of 25 C is used.

Notes

If the reference parameters in the ModuleParameters struct are read from a database or library of parameters (e.g. System Advisor Model), it is important to use the same EgRef and dEgdT values that were used to generate the reference parameters, regardless of the actual bandgap characteristics of the semiconductor. For example, in the case of the System Advisor Model library, created as described in [3], EgRef and dEgdT for all modules were 1.121 and -0.0002677, respectively.

This table of reference bandgap energies (EgRef), bandgap energy temperature dependence (dEgdT), and “typical” airmass response (M) is provided purely as reference to those who may generate their own reference module parameters (a_{ref} , IL_{ref} , $I0_{ref}$, etc.) based upon the various PV semiconductors. Again, we stress the importance of using identical EgRef and dEgdT when generation reference parameters and modifying the reference parameters (for irradiance, temperature, and airmass) per DeSoto’s equations.

Silicon (Si): EgRef = 1.121 dEgdT = -0.0002677

```

`pvl.lib.pvsystem.golden_sect_DataFrame(df, VL, VH, func)`

Vectorized golden section search for finding MPPT from a dataframe timeseries

Parameters `df` : DataFrame

Dataframe containing a timeseries of inputs to the function to be optimized. Each row should represent an independant optimization

VL: float

Lower bound of the optimization

VH: float

Upper bound of the optimization

func: function

Function to be optimized must be in the form `f(dataframe, x)`

Returns `func(df,'V1')` : DataFrame

function evaluated at the optimal point

df['V1']: Dataframe

Dataframe of optimal points

Notes

This function will find the MAXIMUM of a function

`pvlb.pvsystem.physicaliam(K, L, n, theta)`

Determine the incidence angle modifier using refractive index, glazing thickness, and extinction coefficient

physicaliam calculates the incidence angle modifier as described in De Soto et al. “Improvement and validation of a model for photovoltaic array performance”, section 3. The calculation is based upon a physical model of absorption and transmission through a cover. Required information includes, incident angle, cover extinction coefficient, cover thickness

Note: The authors of this function believe that eqn. 14 in [1] is incorrect. This function uses the following equation in its place: $\theta_r = \arcsin(1/n * \sin(\theta))$

Parameters **K** : float

The glazing extinction coefficient in units of 1/meters. Reference [1] indicates that a value of 4 is reasonable for “water white” glass. K must be a numeric scalar or vector with all values ≥ 0 . If K is a vector, it must be the same size as all other input vectors.

L : float

The glazing thickness in units of meters. Reference [1] indicates that 0.002 meters (2 mm) is reasonable for most glass-covered PV panels. L must be a numeric scalar or vector with all values ≥ 0 . If L is a vector, it must be the same size as all other input vectors.

n : float

The effective index of refraction (unitless). Reference [1] indicates that a value of 1.526 is acceptable for glass. n must be a numeric scalar or vector with all values ≥ 0 . If n is a vector, it must be the same size as all other input vectors.

theta : Series

The angle of incidence between the module normal vector and the sun-beam vector in degrees.

Returns **IAM** : float

The incident angle modifier as specified in eqns. 14-16 of [1]. IAM is a column vector with the same number of elements as the largest input vector.

Theta must be a numeric scalar or vector. For any values of theta where $\text{abs}(\theta) > 90$, IAM is set to 0. For any values of theta where $-90 < \theta < 0$, theta is set to $\text{abs}(\theta)$ and evaluated. A warning will be generated if $\text{any}(\theta < 0 \text{ or } \theta > 90)$.

```
pvlib.pvsystem.pwr_optfcn(df, loc)
```

Function to find power from I_from_V

```
pvlib.pvsystem.retrieve_sam(name=None, samfile=None)
```

Retrieve latest module and inverter info from SAM website

This function will retrieve either:

- CEC module database
- Sandia Module database
- Sandia Inverter database

and return it as a pandas dataframe.

Parameters `name` : String

Name can be one of:

- ‘CECMod’ - returns the CEC module database
- ‘SandiaInverter’ - returns the Sandia Inverter database
- ‘SandiaMod’ - returns the Sandia Module database

samfile : String

Absolute path to the location of local versions of the SAM file. If file is specified, the latest versions of the SAM database will not be downloaded. The selected file must be in .csv format.

If set to ‘select’, a dialogue will open allowing the user to navigate to the appropriate page.

Returns A DataFrame containing all the elements of the desired database.

Each column represents a module or inverter, and a specific dataset can be retrieved by the command

Examples

```
>>> invdb = pvsystem.retrieveSAM(name='SandiaInverter')
>>> inverter = invdb.AE_Solar_Energy__AE6_0__277V__277V__CEC_2012_
>>> inverter

```

`pvl.lib.pvsystem.sapm` (*Module*, *Eb*, *Ediff*, *Tcell*, *AM*, *AOI*)

The Sandia PV Array Performance Model (SAPM) generates 5 points on a PV module’s I-V curve (Voc, Isc, Ix, Ixx, Vmp/Imp) according to SAND2004-3535. Assumes a reference cell temperature of 25 C.

Parameters **Module** : Series

A DataFrame defining the SAPM performance parameters

Eb : Series

The direct irradiance incident upon the module (suns). Any $E_e < 0$ are set to 0.

Ediff : Series

The diffuse irradiance incident on module.

Tcell : Series

The cell temperature (degrees C).

AM : Series

Absolute airmass.

AOI : Series

Angle of incidence.

Returns A DataFrame with the columns Isc, Imp, Ix, Ixx, Voc, Vmp, Pmp.

See also:

`retrievesam`, `sapm_celltemp`

Notes

The coefficients from SAPM which are required in Module are:

Module field	Description
Module.c	1x8 vector with the C coefficients $\text{Module.c}(1) = C_0$
Module.Isc0	Short circuit current at reference condition (amps)
Module.Imp0	Maximum power current at reference condition (amps)
Module.AlphaIsc	Short circuit current temperature coefficient at reference condition (1/C)
Module.AlphaImp	Maximum power current temperature coefficient at reference condition (1/C)
Module.BetaVoc	Open circuit voltage temperature coefficient at reference condition (V/C)
Module.mBetaVoc	Coefficient providing the irradiance dependence for the BetaVoc temperature coefficient at reference irradiance (V/C)
Module.BetaVmp	Maximum power voltage temperature coefficient at reference condition
Module.mBetaVmp	Coefficient providing the irradiance dependence for the BetaVmp temperature coefficient at reference irradiance (V/C)
Module.n	Empirically determined “diode factor” (dimensionless)
Module.Ns	Number of cells in series in a module’s cell string(s)

References

`pvlib.pvsystem.sapm_celltemp(irrad, wind, temp, model='open_rack_cell_glassback')`

Estimate cell and module temperatures per the Sandia PV Array Performance model (SAPM, SAND2004-3535), when given the incident irradiance, wind speed, ambient temperature, and SAPM module parameters.

Parameters **irrad** : float or DataFrame

Total incident irradiance in W/m².

wind : float or DataFrame

Wind speed in m/s at a height of 10 meters.

temp : float or DataFrame

Ambient dry bulb temperature in degrees C.

model : string or list

Model to be used.

If string, can be:

- ‘Open_rack_cell_glassback’ (DEFAULT)
- ‘Roof_mount_cell_glassback’
- ‘Open_rack_cell_polymerback’
- ‘Insulated_back_polumerback’
- ‘Open_rack_Polymer_thinfilmm_steel’
- ‘22X_Concentrator_tracker’

If list, supply the following parameters in the following order:

- **a** [float] SAPM module parameter for establishing the upper limit for module temperature at low wind speeds and high solar irradiance (see SAPM eqn. 11).
- **b** [float] SAPM module parameter for establishing the rate at which the module temperature drops as wind speed increases (see SAPM eqn. 11). Must be a scalar.
- **deltaT** [float] SAPM module parameter giving the temperature difference between the cell and module back surface at the reference irradiance, E0.

Returns dict with keys `tcell` and `tmodule`. Values in degrees C.

`sapm`

References

[1] King, D. et al, 2004, “Sandia Photovoltaic Array Performance Model”, SAND Report 3535, Sandia National Laboratories, Albuquerque, NM.

`pvlib.pvsystem.singlediode(Module, IL, IO, Rs, Rsh, nNsVth, **kwargs)`

Solve the single-diode model to obtain a photovoltaic IV curve.

singlediode solves the single diode equation [1]: $I = I_L - I_0 * [\exp((V + I * R_s) / (n N_s V_{th})) - 1] - (V + I * R_s) / R_{sh}$ for I and V when given I_L , I_0 , R_s , R_{sh} , and $n N_s V_{th}$ ($n N_s V_{th} = n * N_s * V_{th}$) which are described later. `pvl_singlediode` returns a struct which contains the 5 points on the I-V curve specified in SAND2004-3535 [3]. If all I_L , I_0 , R_s , R_{sh} , and $n N_s V_{th}$ are scalar, a single curve will be returned, if any are DataFrames (of the same length), multiple IV curves will be calculated.

The input parameters can be calculated using `calcp_params_desoto` from meteorological data.

Parameters **Module** : DataFrame

A DataFrame defining the SAPM performance parameters.

IL : float or DataFrame

Light-generated current (photocurrent) in amperes under desired IV curve conditions.

I0 : float or DataFrame

Diode saturation current in amperes under desired IV curve conditions.

Rs : float or DataFrame

Series resistance in ohms under desired IV curve conditions.

Rsh : float or DataFrame

Shunt resistance in ohms under desired IV curve conditions. May be a scalar or DataFrame, but DataFrames must be of same length as all other input DataFrames.

nNsVth : float or DataFrame

The product of three components. 1) The usual diode ideal factor (n), 2) the number of cells in series (N_s), and 3) the cell thermal voltage under the desired IV curve conditions (V_{th}). The thermal voltage of the cell (in volts) may be calculated as $k * T_{cell} / q$, where k is Boltzmann's constant (J/K), T_{cell} is the temperature of the p-n junction in Kelvin, and q is the elementary charge of an electron (coulombs).

Returns A DataFrame with the following fields. All fields have the same number of rows as the largest input DataFrame:

- `Result.Isc` - short circuit current in amperes.
- `Result.Voc` - open circuit voltage in volts.
- `Result.Imp` - current at maximum power point in amperes.
- `Result.Vmp` - voltage at maximum power point in volts.
- `Result.Pmp` - power at maximum power point in watts.
- `Result.Ix` - current, in amperes, at $V = 0.5 * V_{oc}$.
- `Result.Ixx` - current, in amperes, at $V = 0.5 * (V_{oc} + V_{mp})$.

Other Parameters **NumPoints** : integer

Number of points in the desired IV curve (optional). Must be a finite scalar value. Non-integer values will be rounded to the next highest integer (ceil). If `ceil(NumPoints)` is < 2 , no IV curves will be produced (i.e. `Result.V` and `Result.I` will not be generated). The default value is 0, resulting in no calculation of IV points other than those specified in [3].

See also:

`sapm`, `calcp_params_desoto`

Notes

The solution employed to solve the implicit diode equation utilizes the Lambert W function to obtain an explicit function of $V=f(i)$ and $I=f(V)$ as shown in [2].

`pvlb.pvsystem.snlinverter` (*inverter*, *Vmp*, *Pmp*)

Converts DC power and voltage to AC power using Sandia’s Grid-Connected PV Inverter model

Determine the AC power output of an inverter given the DC voltage, DC power, and appropriate Sandia Grid-Connected Photovoltaic Inverter Model parameters. The output, *ACPower*, is clipped at the maximum power output, and gives a negative power during low-input power conditions, but does NOT account for maximum power point tracking voltage windows nor maximum current or voltage limits on the inverter.

Parameters *inverter* : DataFrame

A DataFrame defining the inverter to be used, giving the inverter performance parameters according to the Sandia Grid-Connected Photovoltaic Inverter Model (SAND 2007-5036) [1]. A set of inverter performance parameters are provided with *pvlb*, or may be generated from a System Advisor Model (SAM) [2] library using *retreivesam*.

Required DataFrame components are:

Field	DataFrame
Inverter.Pac0	AC-power output from inverter based on input power and voltage, (W)
Inverter.Pdc0	DC-power input to inverter, typically assumed to be equal to the PV array maximum power, (W)
Inverter.Vdc0	DC-voltage level at which the AC-power rating is achieved at the reference operating condition, (V)
Inverter.Pso	DC-power required to start the inversion process, or self-consumption by inverter, strongly influences inverter efficiency at low power levels, (W)
Inverter.C0	Parameter defining the curvature (parabolic) of the relationship between ac-power and dc-power at the reference operating condition, default value of zero gives a linear relationship, (1/W)
Inverter.C1	Empirical coefficient allowing <i>Pdco</i> to vary linearly with dc-voltage input, default value is zero, (1/V)
Inverter.C2	empirical coefficient allowing <i>Pso</i> to vary linearly with dc-voltage input, default value is zero, (1/V)
Inverter.C3	empirical coefficient allowing <i>Co</i> to vary linearly with dc-voltage input, default value is zero, (1/V)
Inverter.Pnt	ac-power consumed by inverter at night (night tare) to maintain circuitry required to sense PV array voltage, (W)

Vdc : float or DataFrame

DC voltages, in volts, which are provided as input to the inverter. *Vdc* must be ≥ 0 .

Pdc : float or DataFrame

A scalar or DataFrame of DC powers, in watts, which are provided as input to the inverter. Pdc must be ≥ 0 .

Returns **ACPower** : float or DataFrame

Modeled AC power output given the input DC voltage, Vdc, and input DC power, Pdc. When ACPower would be greater than Pac0, it is set to Pac0 to represent inverter “clipping”. When ACPower would be less than Ps0 (startup power required), then ACPower is set to $-1 \times \text{abs}(\text{Pnt})$ to represent nightly power losses. ACPower is not adjusted for maximum power point tracking (MPPT) voltage windows or maximum current limits of the inverter.

[2] System Advisor Model web page. <https://sam.nrel.gov>.

`pvl-lib.pvsystem.systemdef` (*tmy_meta*, *surftilt*, *surfaz*, *albedo*, *series_modules*, *parallel_modules*)
Generates a dict of system paramters used throughout a simulation.

Parameters **tmy_meta** : dict

meta file generated from a TMY file using `pvl_readtmy2` or `pvl_readtmy3`. It should contain at least the following fields:

meta field	format	description
meta.altitude	Float	site elevation
meta.latitude	Float	site latitude
meta.longitude	Float	site longitude
meta.Name	String	site name
meta.State	String	state
meta.TZ	Float	timezone

surftilt : float or DataFrame

Surface tilt angles in decimal degrees. `surftilt` must be ≥ 0 and ≤ 180 . The tilt angle is defined as degrees from horizontal (e.g. surface facing up = 0, surface facing horizon = 90)

surfaz : float or DataFrame

Surface azimuth angles in decimal degrees. `surfaz` must be ≥ 0 and ≤ 360 . The Azimuth convention is defined as degrees east of north (e.g. North = 0, South=180 East = 90, West = 270).

albedo : float or DataFrame

Ground reflectance, typically 0.1-0.4 for surfaces on Earth (land), may increase over snow, ice, etc. May also be known as the reflection coefficient. Must be ≥ 0 and ≤ 1 .

series_modules : float

Number of modules connected in series in a string.

parallel_modules : int

Number of strings connected in parallel.

Returns Result : dict

A dict with the following fields.

- 'surftilt'
- 'surfaz'
- 'albedo'
- 'series_modules'
- 'parallel_modules'
- 'Lat'
- 'Long'
- 'TZ'
- 'name'
- 'altitude'

`readtmy3`, `readtmy2`

1.6 solarposition module

Calculate the solar position using a variety of methods/packages.

`pvlib.solarposition.calc_time` (*lower_bound, upper_bound, location, attribute, value, pressure=101325, temperature=12, xtol=1e-12*)

Calculate the time between `lower_bound` and `upper_bound` where the attribute is equal to value. Uses PyEphem for solar position calculations.

Parameters `lower_bound` : `datetime.datetime`

`upper_bound` : `datetime.datetime`

`location` : `pvlib.Location` object

`attribute` : str

The attribute of a `pyephem.Sun` object that you want to solve for. Likely options are 'alt' and 'az' (which must be given in radians).

`value` : int or float

The value of the attribute to solve for

`pressure` : int or float, optional

Air pressure in Pascals. Set to 0 for no atmospheric correction.

`temperature` : int or float, optional

Air temperature in degrees C.

`xtol` : float, optional

The allowed error in the result from value

Returns `datetime.datetime`

Raises ValueError

If the value is not contained between the bounds.

AttributeError

If the given attribute is not an attribute of a PyEphem.Sun object.

`pvlib.solarposition.ephemeris` (*time, location, pressure=101325, temperature=12*)

Python-native solar position calculator. The accuracy of this code is not guaranteed. Consider using the built-in `spa_c` code or the PyEphem library.

Parameters **time** : pandas.DatetimeIndex

location : pvlib.Location

Returns DataFrame with the following columns

SunEl : float of DataFrame

Actual elevation (not accounting for refraction) of the sun in decimal degrees, 0 = on horizon. The complement of the True Zenith Angle.

SunAz : Azimuth of the sun in decimal degrees from North. 0 = North to 270 = West

SunZen : Solar zenith angle

ApparentSunEl : float or DataFrame

Apparent sun elevation accounting for atmospheric refraction. This is the complement of the Apparent Zenith Angle.

SolarTime : float or DataFrame

Solar time in decimal hours (solar noon is 12.00).

Other Parameters **pressure** : float or DataFrame

Ambient pressure (Pascals)

temperature : float or DataFrame

Ambient temperature (C)

References

Grover Hughes' class and related class materials on Engineering Astronomy at Sandia National Laboratories, 1985.

`pvlib.solarposition.get_solarposition` (*time, location, method='pyephem', pressure=101325, temperature=12*)

A convenience wrapper for the solar position calculators.

Parameters **time** : pandas.DatetimeIndex

location : pvlib.Location object

method : string

'pyephem' uses the PyEphem package. Default. 'spa' uses the pvlib ephemeris code.

pressure : float

Pascals.

temperature : float

Degrees C.

`pvlib.solarposition.pyephem(time, location, pressure=101325, temperature=12)`

Calculate the solar position using the PyEphem package.

Parameters **time** : pandas.DatetimeIndex

location : pvlib.Location object

pressure : int or float, optional

air pressure in Pascals.

temperature : int or float, optional

air temperature in degrees C.

Returns DataFrame

The DataFrame will have the following columns: apparent_elevation, elevation, apparent_azimuth, azimuth, apparent_zenith, zenith.

`pvlib.solarposition.pyephem_earthsun_distance(time)`

Calculates the distance from the earth to the sun using pyephem.

Parameters **time** : pd.DatetimeIndex

Returns pd.Series. Earth-sun distance in AU.

`pvlib.solarposition.spa(time, location, raw_spa_output=False)`

Calculate the solar position using the C implementation of the NREL SPA code

The source files for this code are located in `./spa_c_files/`, along with a README file which describes how the C code is wrapped in Python.

Parameters **time** : pandas.DatetimeIndex

location : pvlib.Location object

raw_spa_output : bool

If true, returns the raw SPA output.

Returns DataFrame

The DataFrame will have the following columns: elevation, azimuth, zenith.

NREL SPA code: <http://redc.nrel.gov/solar/codesandalgorithms/spa/>

1.7 tmy module

Import TMY2 and TMY3 data.

`pvlib.tmy.interactive_load()`

`pvlib.tmy.parsedate(ymd, hour)`

`pvlib.tmy.parsemeta(columns, line)`

Retrieves metadata from the top line of the tmy2 file.

Parameters **Columns** : string

String of column headings in the header

line : string

Header string containing DataFrame

Returns **meta** : Dict of metadata contained in the header string

`pvlib.tmy.parsetz(UTC)`

`pvlib.tmy.readTMY(string, columns, hdr_columns, fname)`

`pvlib.tmy.readtmy2(filename)`

Read a TMY2 file in to a DataFrame

Note that values contained in the DataFrame are unchanged from the TMY2 file (i.e. units are retained). Time/Date and Location data imported from the TMY2 file have been modified to a “friendlier” form conforming to modern conventions (e.g. N latitude is positive, E longitude is positive, the “24th” hour of any day is technically the “0th” hour of the next day). In the case of any discrepancies between this documentation and the TMY2 User’s Manual ([1]), the TMY2 User’s Manual takes precedence.

If a filename is not provided, the user will be prompted to browse to an appropriate TMY2 file.

Parameters **filename** : string

an optional argument which allows the user to select which TMY2 format file should be read. A file path may also be necessary if the desired TMY2 file is not in the working path. If filename is not provided, the user will be prompted to browse to an appropriate TMY2 file.

Returns **TMYData** : DataFrame

A dataframe, is provided with the following components. Note that for more detailed descriptions of each component, please consult the TMY2 User’s Manual ([1]), especially tables 3-1 through 3-6, and Appendix B.

meta : struct

A struct containing the metadata from the TMY2 file.

See also:

`pvl_makelocationstruct`, `pvl_maketimestruct`, `pvl_readtmy3`

Notes

The structures have the following fields

meta Field	
meta.SiteID	Site identifier code (WBAN number), scalar unsigned integer
meta.StationName	Station name, 1x1 cell string
meta.StationState	Station state 2 letter designator, 1x1 cell string
meta.SiteTimeZone	Hours from Greenwich, scalar double
meta.latitude	Latitude in decimal degrees, scalar double
meta.longitude	Longitude in decimal degrees, scalar double
meta.SiteElevation	Site elevation in meters, scalar double

TMYData Field	Meaning
index	Pandas timeseries object containing timestamps
year	
month	
day	
hour	
ETR	Extraterrestrial horizontal radiation recv'd during 60 minutes prior to timestamp, Wh/m ²
ETRN	Extraterrestrial normal radiation recv'd during 60 minutes prior to timestamp, Wh/m ²
GHI	Direct and diffuse horizontal radiation recv'd during 60 minutes prior to timestamp, Wh/m ²
GHISource	See [1], Table 3-3
GHIUncertainty	See [1], Table 3-4
DNI	Amount of direct normal radiation (modeled) recv'd during 60 minutes prior to timestamp, Wh/m ²
DNISource	See [1], Table 3-3
DNIUncertainty	See [1], Table 3-4
DHI	Amount of diffuse horizontal radiation recv'd during 60 minutes prior to timestamp, Wh/m ²
DHISource	See [1], Table 3-3
DHIUncertainty	See [1], Table 3-4
GHillum	Avg. total horizontal illuminance recv'd during the 60 minutes prior to timestamp, units of 100 lux (e.g. val
GHillumSource	See [1], Table 3-3
GHillumUncertainty	See [1], Table 3-4
DNillum	Avg. direct normal illuminance recv'd during the 60 minutes prior to timestamp, units of 100 lux
DNillumSource	See [1], Table 3-3
DNillumUncertainty	See [1], Table 3-4
DHillum	Avg. horizontal diffuse illuminance recv'd during the 60 minutes prior to timestamp, units of 100 lux
DHillumSource	See [1], Table 3-3
DHillumUncertainty	See [1], Table 3-4
Zenithlum	Avg. luminance at the sky's zenith during the 60 minutes prior to timestamp, units of 10 Cd/m ² (e.g. val
ZenithlumSource	See [1], Table 3-3
ZenithlumUncertainty	See [1], Table 3-4
TotCld	Amount of sky dome covered by clouds or obscuring phenonema at time stamp, tenths of sky
TotCldSource	See [1], Table 3-5, 8760x1 cell array of strings
TotCldUnertainty	See [1], Table 3-6
OpqCld	Amount of sky dome covered by clouds or obscuring phenonema that prevent observing the sky at time st
OpqCldSource	See [1], Table 3-5, 8760x1 cell array of strings
OpqCldUncertainty	See [1], Table 3-6
DryBulb	Dry bulb temperature at the time indicated, in tenths of degree C (e.g. 352 = 35.2 C).
DryBulbSource	See [1], Table 3-5, 8760x1 cell array of strings
DryBulbUncertainty	See [1], Table 3-6
DewPoint	Dew-point temperature at the time indicated, in tenths of degree C (e.g. 76 = 7.6 C).
DewPointSource	See [1], Table 3-5, 8760x1 cell array of strings
DewPointUncertainty	See [1], Table 3-6
RHum	Relative humidity at the time indicated, percent
RHumSource	See [1], Table 3-5, 8760x1 cell array of strings
RHumUncertainty	See [1], Table 3-6
Pressure	Station pressure at the time indicated, 1 mbar
PressureSource	See [1], Table 3-5, 8760x1 cell array of strings
PressureUncertainty	See [1], Table 3-6
Wdir	Wind direction at time indicated, degrees from east of north (360 = 0 = north; 90 = East; 0 = undefined, cal
WdirSource	See [1], Table 3-5, 8760x1 cell array of strings
WdirUncertainty	See [1], Table 3-6
Wspd	Wind speed at the time indicated, in tenths of meters/second (e.g. 212 = 21.2 m/s)
WspdSource	See [1], Table 3-5, 8760x1 cell array of strings
WspdUncertainty	See [1], Table 3-6

Table 1.1 – continued from previous page

TMYData Field	Meaning
Hvis	Distance to discernable remote objects at time indicated (7777=unlimited, 9999=missing data), in tenths of miles
HvisSource	See [1], Table 3-5, 8760x1 cell array of strings
HvisUncertainty	See [1], Table 3-6
CeilHgt	Height of cloud base above local terrain (7777=unlimited, 8888=cirroform, 9999=missing data), in meters
CeilHgtSource	See [1], Table 3-5, 8760x1 cell array of strings
CeilHgtUncertainty	See [1], Table 3-6
Pwat	Total precipitable water contained in a column of unit cross section from Earth to top of atmosphere, in mm
PwatSource	See [1], Table 3-5, 8760x1 cell array of strings
PwatUncertainty	See [1], Table 3-6
AOD	The broadband aerosol optical depth (broadband turbidity) in thousandths on the day indicated (e.g. 114 = 0.114)
AODSource	See [1], Table 3-5, 8760x1 cell array of strings
AODUncertainty	See [1], Table 3-6
SnowDepth	Snow depth in centimeters on the day indicated, (999 = missing data).
SnowDepthSource	See [1], Table 3-5, 8760x1 cell array of strings
SnowDepthUncertainty	See [1], Table 3-6
LastSnowfall	Number of days since last snowfall (maximum value of 88, where 88 = 88 or greater days; 99 = missing data)
LastSnowfallSource	See [1], Table 3-5, 8760x1 cell array of strings
LastSnowfallUncertainty	See [1], Table 3-6
PresentWeather	See [1], Appendix B, an 8760x1 cell array of strings. Each string contains 10 numeric values. The string codes are defined in [1], Appendix B.

References

`pvl-lib.tmy.readtmy3 (filename=None)`

Read a TMY3 file in to a pandas dataframe

Read a TMY3 file and make a pandas dataframe of the data. Note that values contained in the struct are unchanged from the TMY3 file (i.e. units are retained). In the case of any discrepancies between this documentation and the TMY3 User’s Manual ([1]), the TMY3 User’s Manual takes precedence.

If a filename is not provided, the user will be prompted to browse to an appropriate TMY3 file.

Parameters `filename` : string

An optional argument which allows the user to select which TMY3 format file should be read. A file path may also be necessary if the desired TMY3 file is not in the MATLAB working path.

Returns `TMYDATA` : DataFrame

A pandas dataframe, is provided with the components in the table below. Note that for more detailed descriptions of each component, please consult the TMY3 User’s Manual ([1]), especially tables 1-1 through 1-6.

meta : struct

struct of meta data is created, which contains all site metadata available in the file

See also:

`pvl_makelocationstruct`, `pvl_readtmy2`

Notes

meta field	format	description
meta.altitude	Float	site elevation
meta.latitude	Float	site latitude
meta.longitude	Float	site longitude
meta.Name	String	site name
meta.State	String	state
meta.TZ	Float	timezone
meta.USAF	Int	USAF identifier

TMYData field	description
TMYData.Index	A pandas datetime index. NOTE, the index is currently timezone unaware, and times are set to local time.
TMYData.ETR	Extraterrestrial horizontal radiation recv'd during 60 minutes prior to timestamp, Wh/m ²
TMYData.ETRn	Extraterrestrial normal radiation recv'd during 60 minutes prior to timestamp, Wh/m ²
TMYData.GHI	Direct and diffuse horizontal radiation recv'd during 60 minutes prior to timestamp, Wh/m ²
TMYData.GHISource	See [1], Table 1-4
TMYData.GHIUncertainty	Uncertainty based on random and bias error estimates see [2]
TMYData.DNI	Amount of direct normal radiation (modeled) recv'd during 60 minutes prior to timestamp, Wh/m ²
TMYData.DNISource	See [1], Table 1-4
TMYData.DNIUncertainty	Uncertainty based on random and bias error estimates see [2]
TMYData.DHI	Amount of diffuse horizontal radiation recv'd during 60 minutes prior to timestamp, Wh/m ²
TMYData.DHISource	See [1], Table 1-4
TMYData.DHIUncertainty	Uncertainty based on random and bias error estimates see [2]
TMYData.GHillum	Avg. total horizontal illuminance recv'd during the 60 minutes prior to timestamp, lx
TMYData.GHillumSource	See [1], Table 1-4
TMYData.GHillumUncertainty	Uncertainty based on random and bias error estimates see [2]
TMYData.DNillum	Avg. direct normal illuminance recv'd during the 60 minutes prior to timestamp, lx
TMYData.DNillumSource	See [1], Table 1-4
TMYData.DNillumUncertainty	Uncertainty based on random and bias error estimates see [2]
TMYData.DHillum	Avg. horizontal diffuse illuminance recv'd during the 60 minutes prior to timestamp, lx
TMYData.DHillumSource	See [1], Table 1-4
TMYData.DHillumUncertainty	Uncertainty based on random and bias error estimates see [2]
TMYData.Zenithlum	Avg. luminance at the sky's zenith during the 60 minutes prior to timestamp, cd/m ²
TMYData.ZenithlumSource	See [1], Table 1-4
TMYData.ZenithlumUncertainty	Uncertainty based on random and bias error estimates see [1] section 2.10
TMYData.TotCld	Amount of sky dome covered by clouds or obscuring phenomenon at time stamp, tenths of sky
TMYData.TotCldSource	See [1], Table 1-5, 8760x1 cell array of strings
TMYData.TotCldUncertainty	See [1], Table 1-6
TMYData.OpqCld	Amount of sky dome covered by clouds or obscuring phenomenon that prevent observing the sky at time stamp, tenths of sky
TMYData.OpqCldSource	See [1], Table 1-5, 8760x1 cell array of strings

`pvlib.tmy.recolumn(TMY3)`

1.8 tools module

Collection of functions used in `pvlib_python`

`pvlib.tools.asind(number)`

Inverse Sine returning an angle in degrees

Parameters `number` : float

Input number

Returns `result` : float

arcsin result

`pvlib.tools.cosd(angle)`

Cosine with angle input in degrees

Parameters *angle* : float

Angle in degrees

Returns *result* : float

Cosine of the angle

`pvlib.tools.datetime_to_djd(time)`

Converts a datetime to the Dublin Julian Day

Parameters *time* : datetime.datetime

time to convert

Returns float

fractional days since 12/31/1899+0000

`pvlib.tools.djd_to_datetime(djd, tz='UTC')`

Converts a Dublin Julian Day float to a datetime.datetime object

Parameters *djd* : float

fractional days since 12/31/1899+0000

tz : str

timezone to localize the result to

Returns datetime.datetime

The resultant datetime localized to *tz*

`pvlib.tools.localize_to_utc(time, location)`

Converts or localizes a time series to UTC.

Parameters *time* : datetime.datetime, pandas.DatetimeIndex,

or pandas.Series/DataFrame with a DatetimeIndex.

location : pvlib.Location object

Returns pandas object localized to UTC.

`pvlib.tools.sind(angle)`

Sine with angle input in degrees

Parameters *angle* : float

Angle in degrees

Returns *result* : float

Sin of the angle

`pvlib.tools.tand(angle)`

Tan with angle input in degrees

Parameters *angle* : float

Angle in degrees

Returns *result* : float

Tan of the angle
